Regular expressions (regex, regex) are patterns that match character strings

They can be thought of as describing a set of strings.

<https://eduassistpro.github.io>

**Find and replace:** Substitute so  
substring (sed, vi).  
s/ridd/gillard/g  
s/[dD]og/Canis lupus familiari

- **Validate or test:** Check if new string is correct (awk, Python, Perl).  
`$input =~ /gillard/`  
`$input =~ /^[A-Z0-9._%+-]+@[A-Z0-9.-]+\.[A-Z]{2,4}$/`

The four main concepts of regex mirror the four types of structure in imperative programming languages.

/cat/

(pattern)

/cat|dog/

do thing

else:

do other thing

Repetition:

while True:

i += 1

/(cat)\*/

### Pattern matching

### Regular expressions

### Regex

### Pattern language

### Pattern programming

As the examples above show, regular expressions are a mix of literal characters and command or control characters. For example

- `.` means “match the character `.`”

- `|` means *or*

<https://eduassistpro.github.io>

- `\$` means “match the character `$`”, a

- `\\` means “match the character `\`”.

Beware, some tools have different metacharacters than the same as `.` in standard regex.

And in some cases `\` turns a character into a metacharacter.

Here, I sometimes use `/` as a pattern delimiter. In some tools, it too is a metacharacter.

The foundation of regex is literal matching:

Assignment Project Exam Help  
/knowledge/

https://eduassistpro.github.io

/over priced/ won't match "overpriced"

Add WeChat edu\_assist\_pr  
Substrings are uninterpreted; they are words or have any specific semantics  
/lane/ will match "planet"

Another special case is newline. Many tools that incorporate regex are **line-oriented**, and either cannot match across a line break or do so in idiosyncratic ways.

The wildcard `.` is the most basic metacharacter.

- Matches any single character (except a newline); good for crossword puzzles:

<https://eduassistpro.github.io>

Add WeChat `edu_assist_pro`

The anchors `^` and `$` match the start and end of a line, respectively.

- `> egrep '^..n.wl.d..$' .../local/words.txt`  
knowledge

## Assignment Project Exam Help

The metacharacter expresses alternation or disjunction

- `/a|b|c/` matches “a”, “b”, or “c”.

<https://eduassistpro.github.io>

the  
parentheses in the last example are neces

Add WeChat edu\_assist\_pr

Check – what is the difference between

- `> egrep 'edling$' /usr/share/dic`
- `> egrep '(edling)$' /usr/share/dict/words`

The precise number of characters to match may be unknown; instead, we specify a repetition construction.

Some repetitions involve an arbitrary number:

- `*`: zero or more of the preceding element

<https://eduassistpro.github.io>

will always match a complete string and `a.*b` will pick up the *last* “b” in the string.

[Add WeChat edu\\_assist\\_pro](#)

Some inlines we care, but only approximate

- `{n}`: exactly  $n$  of the preceding ele
- `{m,n}`: between  $m$  and  $n$  (inclusive) of the preceding element
- `{n,}`:  $n$  or more of the preceding element
- `{,m}`: up to  $m$  of the preceding element

For example, `labell?ing` matches “labeling”, “labelling”.

Sometimes, rather than one particular character or any character, we want to match any of a set of characters.

Some possible character classes:

■ `/^[A-Z][a-z]*/`

■ `/[A-Z,a-z]+/`

<https://eduassistpro.github.io>

Add WeChat edu\_assist\_pro

Observe that ranges can be used to denote th

Observe also that within `[,]`, metacharacters may be used in their literal meaning. For example, in some languages, the class `[\$]` matches `"\"` or `"$"`.

# Assignment Project Exam Help

A second use of the `^` metacharacter is to negate character classes.

`/[^A-Za-z]/` matches any non-alpha character.

<https://eduassistpro.github.io/negs>

What do these match?

- `/[~0-9]/`
- `/[~']/'`
- `/<[~>]>/`

Add WeChat edu\_assist\_pr

Some character classes are used so frequently that they have names:

- `[0-9] = [[:digit:]] = \d`

- `[a-zA-Z0-9_] = [[:word:]] = \w`

- 

- `[^0-9] = \D`

- `[^a-zA-Z0-9_] = \W`

- `[^\w\t\r\n] = \s`

Beware again: Which named character classes are available and how they are represented depends on the software you use.

# Assignment Project Exam Help

Placing a pattern in parentheses leads to the match being stored as a variable.

<https://eduassistpro.github.io>, there is no

Example: What does `/([a-zA-Z]+) +`

Add WeChat [edu\\_assist\\_pro](https://eduassistpro.github.io)

Example: `s/([A-Z])[a-z]+ ([A-Z][a-z]+)/\1. \2/`

Now we can parse the regex from earlier on:

```
/^[A-Z0-9._%+-]+@[A-Z0-9.-]+\.[A-Z]{2,4}$/
```

<https://eduassistpro.github.io>

Add WeChat [edu\\_assist\\_pr](#)

- `[A-Z0-9.-]+`
- `\.`: followed by a dot
- `[A-Z]{2,4}$`: followed by 2-4 uppercase letters

- What do you think this pattern is for?
- How might this pattern be improved?

Pattern programming

There are several pattern-based programming languages, in particular Python and Perl. There are also good command-line tools, in particular sed and awk. (Perl is also used in this way.)

<https://eduassistpro.github.io>

Add WeChat [edu\\_assist\\_pro](#)

- Code is C-like (i.e., Java-like, C++-lik
- Lines of input are parsed into fields, and \$1, \$2, \$3, ...
- A line of input is only processed if it matches a pattern.
- Fields may be tested to see if they match a pattern.
